Modeling the cumulative incidence function of clustered competing risks data: a multinomial GLMM approach

Semana Acadêmica de Estatística, UFPR

Henrique Laureano (.github.io)
IPPPP & LEG @ UFPR

September 13, 2021

Giving context: defining where we are and what we did

Object

- Handle clustered competing risks data (a kind of failure time data) through the cumulative incidence function (CIF).

Goal

- Perform maximum likelihood estimation in terms of a full likelihood formulation based on Cederkvist et al. (2019)'s CIF specification (**Scheike's**).

Contribution

- The full likelihood formulation is in terms of a generalized linear mixed model (GLMM) - a conditional approach (with fixed and random/latent effects);
- The optimization and inference are tacked down via an efficient model implementation with the use of *state-of-art* computational libraries (Kristensen et al. (2016)'s TMB).

Outline

Clustered competing risk data

Key ideas:

1. Clustered: groups with a dependence structure (e.g. families);
2. Causes competing by *something*;
3. Occurrence time of this *something*.

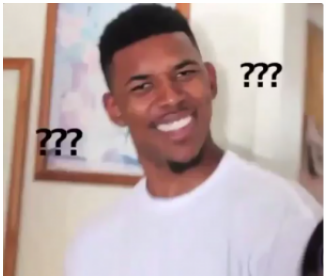
Something?

- **Failure** of an industrial or electronic component;
- **Occurrence** or **cure** of a disease or some biological process;
- **Progress** of a patient clinic state.

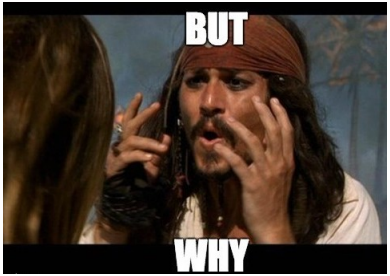
Independent of the application, always the same framework

Cluster	ID	Cause 1	Cause 2	Censorship	Time	Feature
1	1	Yes	No	No	10	A
1	2	No	No	Yes	8	A
2	1	No	No	Yes	7	B
2	2	No	Yes	No	5	A

Modeling clustered competing risks data



What?



Why?

How?

Modeling failure time data

First of all, we have to choose which scale we model the **survival experience**.

1. Usually, is in the

$$\text{hazard (failure rate) scale}: \quad \lambda(t \mid \text{features}) = \lambda_0(t) \times c(\text{features}). \tag{1}$$

We have a Equation 1 for each competing cause.

The cluster dependence is something actually not measured...

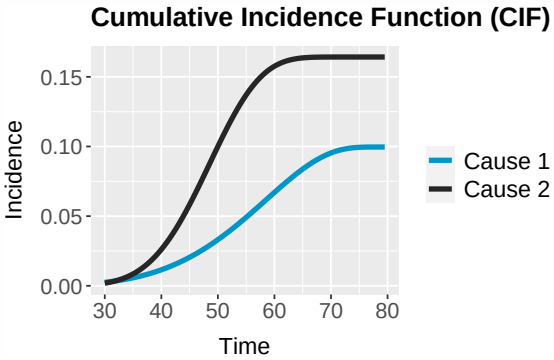
Not measured dependence $\rightarrow$ **random/latent effects** $\rightarrow$ Frailty models.

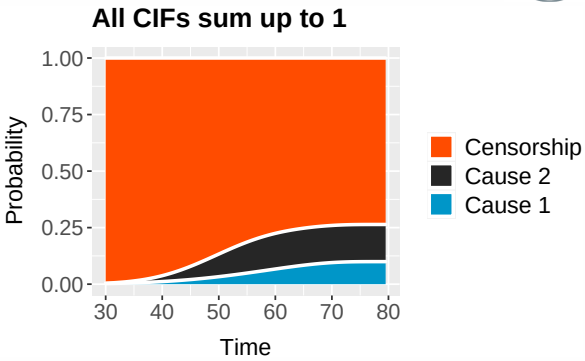
Frailty-based models for (multiple) survival experiences turn out in challengeable likelihood functions with inference routines mostly done via

- Elaborated and slow expectation–maximization (EM) algorithms;
- Inefficient Markov chain Monte Carlo (MCMC) schemes.

2. *Not* usually, the probability scale.

Probability scale $\rightarrow$ Cause-specific CIF





i.e., $\text{CIF} = \mathbb{P}[\text{ failure time} \leqslant t, \text{ a given cause} \mid \text{features \& latent effects }]$.

Common applications: *family studies*.

↳ Keywords: *within-family/cluster dependence*; *age at disease onset*; *populations*.

Cederkvist et al. (2019)'s CIF specification

For two competing causes of failure,
the cause-specific CIFs are specified in the following manner

$$F_k(t \mid \boldsymbol{x},\ u_1,\ u_2,\ \eta_k) = \underbrace{\pi_k(\boldsymbol{x},\ u_1,\ u_2)}_{\substack{\text{cluster-specific}\\ \text{risk level}}} \times \underbrace{\Phi[w_k g(t) - \boldsymbol{x}\gamma_k - \eta_k]}_{\substack{\text{cluster-specific}\\ \text{failure time trajectory}}}, \quad t > 0, \quad k = 1,\ 2, \qquad (2)$$

with

1. $\pi_k(\boldsymbol{x}, \boldsymbol{u}) = \exp\{\boldsymbol{x}\beta_k + u_k\} \Big/ \left(1 + \sum_{m=1}^{K-1} \exp\{\boldsymbol{x}\beta_m + u_m\}\right), \quad k = 1,\ 2, \quad K = 3;$
2. $\Phi(\cdot)$ is the cumulative distribution function of a standard Gaussian distribution;
3. $g(t) = \operatorname{arctanh}(2t/\delta - 1), \quad t \in (0,\ \delta), \quad g(t) \in (-\infty,\ \infty).$

In Cederkvist et al. (2019), this CIF specification is modeled under a pairwise composite likelihood approach (Lindsay 1988; Varin, Reid, and Firth 2011).

Our contribution: a full likelihood analysis

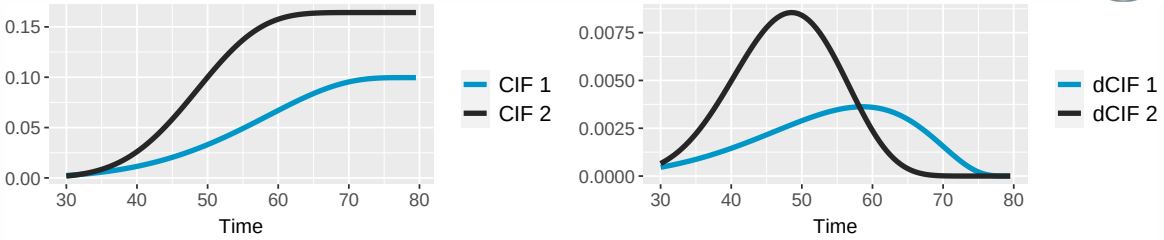
For two competing causes of failure, a subject i, in the cluster j, in time t, we have

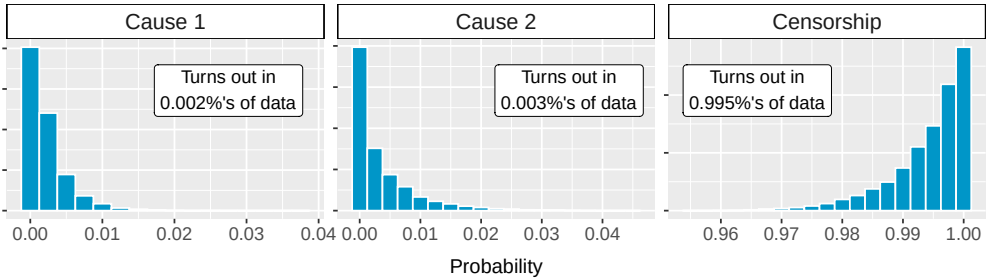
$$y_{ijt} \mid \underbrace{\{u_{1j}, u_{2j}, \eta_{1j}, \eta_{2j}\}}_{\text{latent effects}} \sim \text{Multinomial}(p_{1ijt}, p_{2ijt}, p_{3ijt})$$

$$\begin{bmatrix} u_1 \\ u_2 \\ \eta_1 \\ \eta_2 \end{bmatrix} \sim \text{Multivariate Normal} \left(\begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} \sigma^2_{u_1} & \text{cov}(u_1, u_2) & \text{cov}(u_1, \eta_1) & \text{cov}(u_1, \eta_2) \\ & \sigma^2_{u_2} & \text{cov}(u_2, \eta_1) & \text{cov}(u_2, \eta_2) \\ & & \sigma^2_{\eta_1} & \text{cov}(\eta_1, \eta_2) \\ & & & \sigma^2_{\eta_2} \end{bmatrix} \right)$$

$$\begin{aligned} p_{kijt} &= \frac{\partial}{\partial t} F_k(t \mid \boldsymbol{x}, \boldsymbol{u}, \eta_k) \\ &= \frac{\exp\{\boldsymbol{x}_{kij}\beta_k + u_{kj}\}}{1 + \sum_{m=1}^{K-1} \exp\{\boldsymbol{x}_{mij}\beta_m + u_{mj}\}} \\ &\times w_k \frac{\delta}{2\delta t - 2t^2} \, \phi \left(w_k \text{arctanh} \left(\frac{t - \delta/2}{\delta/2} \right) - \boldsymbol{x}_{kij}\gamma_k - \eta_{kj} \right), \quad k = 1, \, 2. \end{aligned} \tag{3}$$

Simulating from the model





bindwidth=0.0025

Marginal likelihood function for two competing causes

$$
\begin{aligned}
L(\boldsymbol{\theta}; y) &= \prod_{j=1}^{J} \int_{\Re^4} \pi(y_j \mid \boldsymbol{r}_j) \times \pi(\boldsymbol{r}_j)\, \mathrm{d}\boldsymbol{r}_j \\
&= \prod_{j=1}^{J} \int_{\Re^4} \underbrace{\left\{ \prod_{i=1}^{n_j} \prod_{t=1}^{n_{ij}} \left(\frac{(\sum_{k=1}^{K} y_{kijt})!}{y_{1ijt}!\, y_{2ijt}!\, y_{3ijt}!} \prod_{k=1}^{K} p_{kijt}^{y_{kijt}} \right) \right\}}_{\text{fixed effect component}} \times \\
&\qquad \underbrace{(2\pi)^{-2} |\Sigma|^{-1/2} \exp\left\{ -\frac{1}{2} \boldsymbol{r}_j^{\top} \Sigma^{-1} \boldsymbol{r}_j \right\}}_{\text{latent effect component}} \mathrm{d}\boldsymbol{r}_j \\
&= \prod_{j=1}^{J} \int_{\Re^4} \underbrace{\left\{ \prod_{i=1}^{n_j} \prod_{t=1}^{n_{ij}} \prod_{k=1}^{K} p_{kijt}^{y_{kijt}} \right\}}_{\text{fixed effect}} \underbrace{(2\pi)^{-2} |\Sigma|^{-1/2} \exp\left\{ -\frac{1}{2} \boldsymbol{r}_j^{\top} \Sigma^{-1} \boldsymbol{r}_j \right\}}_{\text{latent effect component}} \mathrm{d}\boldsymbol{r}_j, \qquad (4)
\end{aligned}
$$

with p_{kijt} from Equation 3 and where $\boldsymbol{\theta} = [\beta\ \gamma\ \boldsymbol{w}\ \boldsymbol{\sigma^2}\ \boldsymbol{\rho}]^{\top}$ is the parameters vector.

TMB: Template Model Builder

Kristensen et al. (2016).

An R (R Core Team 2021) package for the quickly implementation of complex random effect models through simple C++ templates.

Workflow

1. Write your objective function in a `.cpp` through a `#include <TMB.hpp>`;
2. Compile and load it in R via `TMB::compile()` and `base::dyn.load(TMB::dynlib())`;
3. Compute your objective function derivatives with `obj <- TMB::MakeADFun()`;
4. Perform the model fitting, `opt <- base::nlminb(obj$par, obj$fn, obj$gr)`;
5. Compute the parameters standard deviations, `TMB::sdreport(obj)`.

TMB: Template Model Builder

Key features:

1. Automatic differentiation;
   The state-of-art in derivatives computation
2. Laplace approximation.
   An efficient fashion to approximate the latent effect integrals

A code example:

emacs@laureano

```
// PARALLEL LOGISTIC MIXED MODEL
#include <TMB.hpp>
template<class Type>
Type objective_function<Type>::operator() ()
{
  DATA_VECTOR(y); DATA_SPARSE_MATRIX(Z); DATA_SCALAR(n);
  PARAMETER(beta);
  PARAMETER(logsd);            Type sd = exp(logsd);
  PARAMETER_VECTOR(u); vector<Type> Zu = Z*u;
  vector<Type>  risk = exp(beta+Zu);
  vector<Type> level = 1+risk;
  vector<Type>  prob = risk/level;
  parallel_accumulator<Type> nll(this);
  nll -= dnorm(u, Type(0), sd, true).sum();
  nll -= dbinom(y, n, prob, true).sum();
  ADREPORT(sd);
  return nll;
}
```

-:--- mixedlogistic_parallel.cpp All (19,0) (TMB//l WS)

For details about TMB, AD, and Laplace approximation: Laureano (2021).

Simulation study model designs

Risk model

Latent effects only on the risk level i.e.,

$$\Sigma = \begin{bmatrix} \sigma^2_{u_1} & \mathrm{cov}_{u_1,u_2} \\ & \sigma^2_{u_2} \end{bmatrix}.$$

Time model

Latent effects only on the failure time trajectory level i.e.,

$$\Sigma = \begin{bmatrix} \sigma^2_{\eta_1} & \mathrm{cov}_{\eta_1,\eta_2} \\ & \sigma^2_{\eta_2} \end{bmatrix}.$$

Block-diag model

Latent effects on the risk and time levels without cross-correlations i.e.,

$$\Sigma = \begin{bmatrix} \sigma^2_{u_1} & \mathrm{cov}_{u_1,u_2} & 0 & 0 \\ & \sigma^2_{u_2} & 0 & 0 \\ & & \sigma^2_{\eta_1} & \mathrm{cov}_{\eta_1,\eta_2} \\ & & & \sigma^2_{\eta_2} \end{bmatrix}.$$

Complete model

A *complete* latent effects structure i.e.,

$$\Sigma = \begin{bmatrix} \sigma^2_{u_1} & \mathrm{cov}_{u_1,u_2} & \mathrm{cov}_{u_1,\eta_1} & \mathrm{cov}_{u_1,\eta_2} \\ & \sigma^2_{u_2} & \mathrm{cov}_{u_2,\eta_1} & \mathrm{cov}_{u_2,\eta_2} \\ & & \sigma^2_{\eta_1} & \mathrm{cov}_{\eta_1,\eta_2} \\ & & & \sigma^2_{\eta_2} \end{bmatrix}.$$

Simulation study setup

Four latent effects structures:

1. Risk model;
2. Time model;
3. Block-diag model;
4. Complete model.

Two CIF configurations:

Low max incidence ≈ 0.15; **High** max incidence ≈ 0.60.

For each of those $4 \times 2 = 8$ scenarios, we vary the sample and cluster sizes:

5000 data points	*30000 data points*	*60000 data points*
• 2500 clusters of **size 2**;	• 15000 clusters of **size 2**;	• 30000 clusters of **size 2**;
• 1000 clusters of **size 5**;	• 6000 clusters of **size 5**;	• 12000 clusters of **size 5**;
• 500 clusters of **size 10**.	• 3000 clusters of **size 10**.	• 6000 clusters of **size 10**.

$8 \times 3 \times 3 = 72$ scenarios.
For each scenario, we simulate **500** samples. $72 \times 500 = 36000$ model fittings.

Simulation study results

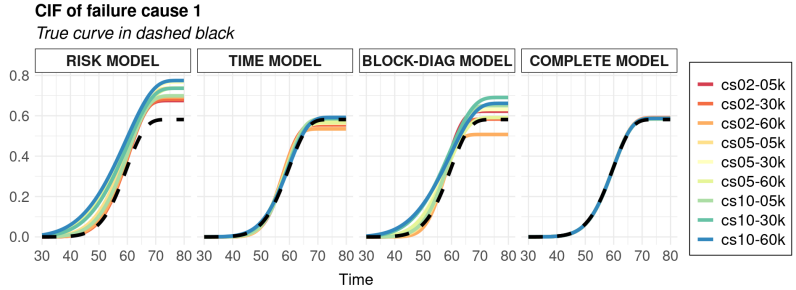
First of all, the **time**.

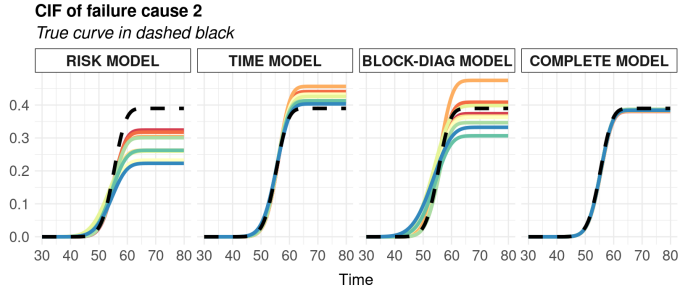
- The *non-complete* models (2D Laplace aprox.) are kind of fast, taking always **less than 5 min**.
- In the most expensive scenarios (30K 4D Laplaces), **the complete model takes 30 min**.
  In a **full R** implementation with 10K 4D Laplaces, it **took 30hrs**. **TMB is fast**.
- We also did a Bayesian analysis via Stan/NUTS-HMC (Stan Development Team 2020).
  - **1 week of parallelized processing** for a 2500 size 2 clusters scenario with tuned NUTS. This just reinforces the MCMC impracticability for some complex models.

Parameters estimation.

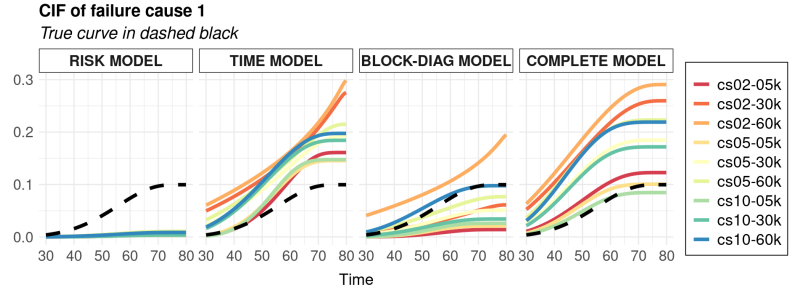
- The *non-complete* models fail to learn the data.
  They appear to be *not structured enough* to capture the data characteristics.

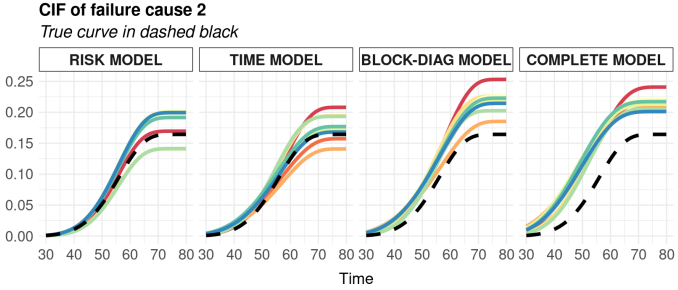
Simulation study results: High CIF scenario





Simulation study results: Low CIF scenario





Take-home message

The complete model works.

1. It works better in the high CIF scenarios;
2. As expected, as the sample size increases the results get better;
3. We do not see any considerable performance difference between cluster/family sizes;
4. Satisfactory full likelihood analysis under the maximum likelihood estimation framework.

What else can we do?

1. We can try a marginal approach e.g., an McGLM (Bonat and Jørgensen 2016);
2. We can also try a copula (Embrechts 2009), on maybe two fronts:
   1) for a full specification; 2) to accommodate the within-cluster dependence.
