| | |
| Exercise 2: dist. Gaussiana bivariada | 9 |
| (a) Matriz de informação de Fisher | 10 |
| (b) Obtenha a verossimilhança conjunta de (σ^2, ρ) e compare I_{22} com I_{22}^{-1} | 12 |
| (c) Investigue como a aproximação quadrática se comporta. Tente transformações de ρ e σ^2 para obter uma função de verossimilhança mais regular | 15 |
| (d) Compare a verossimilhança de ρ baseada na transformação z de Fisher com a verossimilhança perfilhada | 19 |
| | |
| Exercise 3: regressão Gaussiana | 22 |
| (a) Encontre a função de verossimilhança | 22 |
| (b) Encontre as estimativas de máxima verossimilhança. | 23 |
| (c) Obtenha a verossimilhança conjunta para os parâmetros β_0 e β_1 | 23 |
| Considerando σ fixo com valor igual à sua estimativa | 23 |
| Obtendo a verossimilhança perfilhada em relação a σ | 25 |
| (d) Obtenha a verossimilhança perfilhada para β_0 e β_1 individualmente | 26 |
| | |
| Exercise 4: regressão Gaussiana censurada | 27 |
| (a) Encontre a função de verossimilhança | 28 |
| (b) Encontre as estimativas de máxima verossimilhança. | 28 |
| (c) Obtenha a verossimilhança conjunta para os parâmetros β_0 e β_1 | 29 |
| Considerando σ fixo com valor igual à sua estimativa | 29 |
| Obtendo a verossimilhança perfilhada em relação a σ | 30 |
| (d) Obtenha a verossimilhança perfilhada para β_0 e β_1 individualmente | 32 |

Exercice 1: dist. Gaussiana com dados censurados/intervalares

Foram tomadas as seguintes observações independentes de uma v.a. $X \sim \text{Normal}(\mu, \sigma^2)$.

- 56.4, 54.2, 65.3, 49.2, 50.1, 56.9, 58.9, 62.5, 70, 61.
- Sabe-se que outras 5 observações são menores que 50.
- Sabe-se que outras 3 observações são maiores que 65.

(a) Escrever a função de verossimilhança.

The likelihood can be expressed as

$$\begin{aligned} L(\theta) &= \left(\prod_{i=1}^{10} f(x_i) \right) \times (F(50))^5 \times (1 - F(65))^3 \\ &= \left(\prod_{i=1}^{10} \phi\left(\frac{y_i - \mu}{\sigma}\right) \right) \times \left(\Phi\left(\frac{50 - \mu}{\sigma}\right) \right)^5 \times \left(1 - \Phi\left(\frac{65 - \mu}{\sigma}\right) \right)^3 \\ l(\theta) &= \sum_{i=1}^{10} \log \phi\left(\frac{y_i - \mu}{\sigma}\right) + 5 \log \Phi\left(\frac{50 - \mu}{\sigma}\right) + 3 \log \left(1 - \Phi\left(\frac{65 - \mu}{\sigma}\right)\right). \end{aligned}$$

<r code>

```
data_1 <- c(56.4, 54.2, 65.3, 49.2, 50.1, 56.9, 58.9, 62.5, 70, 61)
intervAussian_lkl <- function(mu, sigma) {
  component_1 <- sum(dnorm(data_1, mean = mu, sd = sigma, log = TRUE))
  component_2 <- 5 * log(pnorm(50, mean = mu, sd = sigma))
  component_3 <- 3 * log(1 - pnorm(65, mean = mu, sd = sigma))
  lkl <- component_1 + component_2 + component_3
  return(-lkl) ## minus, since the optim routine performs a minimization
}
```

(b) Obter as estimativas de máxima verossimilhança.

<r code>

```
model_fit <- mle2(intervAussian_lkl,
  start = list("mu" = mean(data_1), "sigma" = sd(data_1)))
(par_est <- model_fit@coef)
```

```

mu      sigma
56.33051 11.13274

```

FYI: In the ten points sample we have $\bar{x} = 58.45$ and $s^2 = 6.527$.

(c) Obter as verossimilhanças perfilhadas.

To obtain the likelihood profile for μ we need to create a grid of μ 's and for each value of this grid find the value, $\hat{\sigma}_\mu$, that maximizes the profile likelihood. We do this for μ and σ , the results can be seen in Figure 1.

```

<r code>

intervAussian_profile <- function(grid, fun, par_est, xlab, main) {
  ggplot() +
    geom_line(aes(x = grid, y = sapply(grid, fun)), size = 1.5) +
    geom_vline(xintercept = par_est, linetype = "dashed") +
    labs(x = xlab, y = NULL, title = main) +
    theme_minimal()
}

grid.arrange(
  intervAussian_profile(
    grid = seq(32, 77, .5),
    fun = function(i) {
      logLik(mle2(intervAussian_lkl,
                  start = list("sigma" = sd(data_1)),
                  data = list("mu" = i)))
    }, par_est = par_est[1], xlab = expression(mu),
    main = expression(
      "logLik for the optimal" ~ sigma ~ "given a fixed" ~ mu)),
  intervAussian_profile(
    grid = seq(5, 50, .5),
    fun = function(i) {
      logLik(mle2(intervAussian_lkl,
                  start = list("mu" = mean(data_1)),
                  data = list("sigma" = i)))
    }, par_est = par_est[2], xlab = expression(sigma),
    main = expression(
      "logLik for the optimal" ~ mu ~ "given a fixed" ~ sigma)),
  ncol = 2)

```

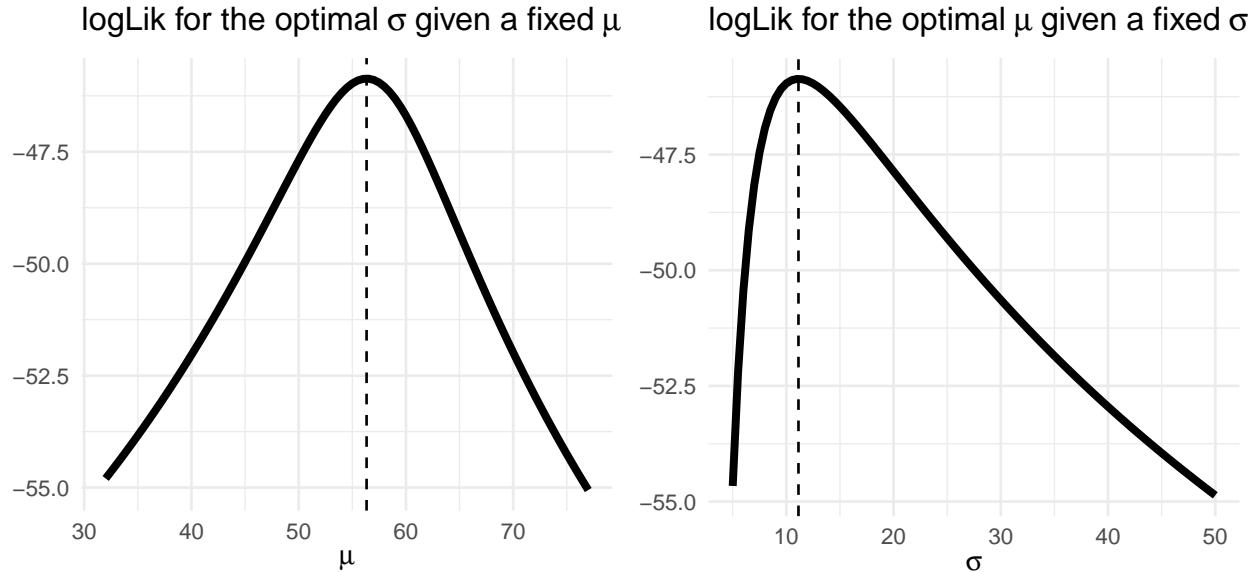

Figure 1: Profile log-likelihoods for μ and σ in a Gaussian sample made of interval/censored data. In dashed, the respective MLE's.

(d) Obter os erro-padrão das estimativas.

```
<r code>
sqrt(diag(model_fit@vcov))

      mu      sigma
2.794350 2.791622
```

(e) Obter a aproximação quadrática da verossimilhança.

```
<r code>
intervAussian_deviance <- function(mu_grid, sigma_grid) {
  lkl_grid <- intervAussian_lkl(mu_grid, sigma_grid)
  lkl_est <- intervAussian_lkl(par_est[1], par_est[2])
  return(2 * (lkl_grid - lkl_est))
}
intervAussian_deviance <- Vectorize(intervAussian_deviance,
                                       c("mu_grid", "sigma_grid"))
intervAussian_taylor <- function(mu, sigma) {
  par_grid <- c(mu, sigma)
```

```

half <- (par_grid - model_fit@coef)
Ie <- solve(model_fit@vcov)
taylor <- logLik(model_fit) - .5 * half %*% Ie %*% half
return(taylor)
}

  geom_vline(xintercept = par_est[1], col = "white") +
  geom_hline(yintercept = par_est[2], col = "white")

```

Deviance contours

MLE's, in white.

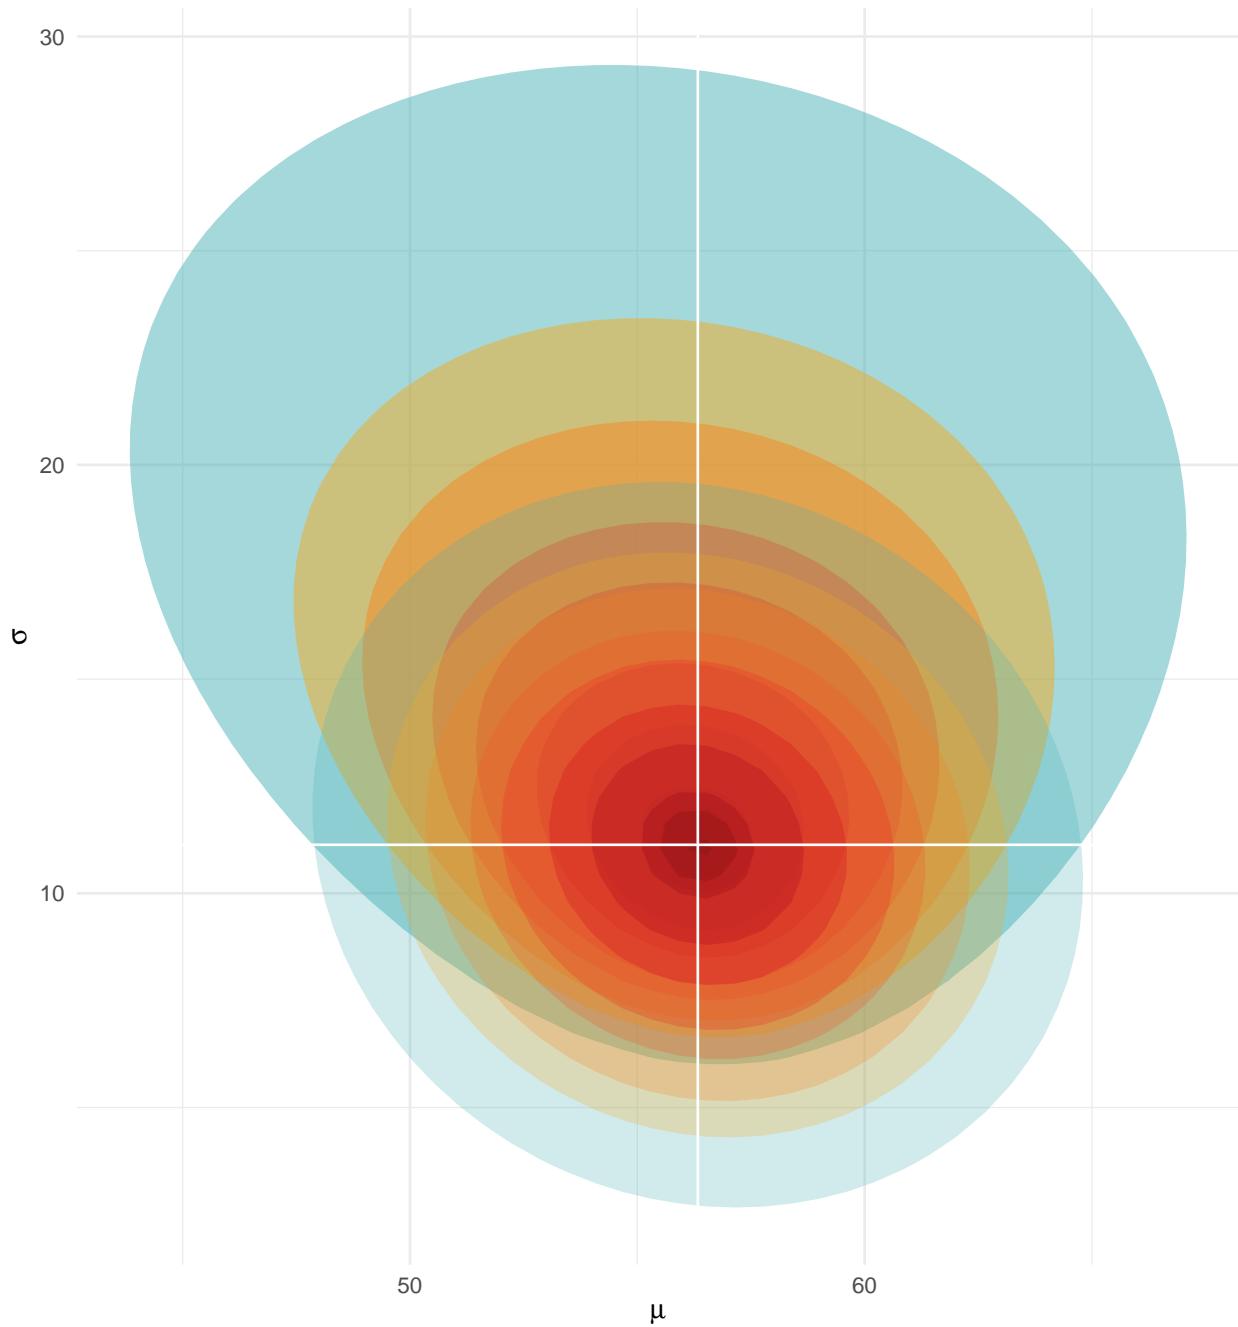

Figure 2: Deviances for the censored/interval Gaussian data. The bigger deviance is the true one, based in the log-likelihood. The smaller one, well-behaved, is based in the quadratic approximation (2nd order taylor approximation) of the log-likelihood.

(f) Obter intervalos de confiança (verossimilhança e Wald) para os parâmetros.

In Figure 3 we see that the regions obtained from the two approaches are quite similar.

<r code>

```
mu_grid <- seq(55, 57.5, length.out = 50)
sigma_grid <- seq(10, 12.5, length.out = 50)

deviance_grid <- outer(mu_grid, sigma_grid, FUN = intervAussian_deviance)

       title = "99 and 95% deviance contours",
       subtitle = "MLE's, in white.") +
  geom_vline(xintercept = par_est[1], col = "white") +
  geom_hline(yintercept = par_est[2], col = "white")
```

99 and 95% deviance contours

MLE's, in white.

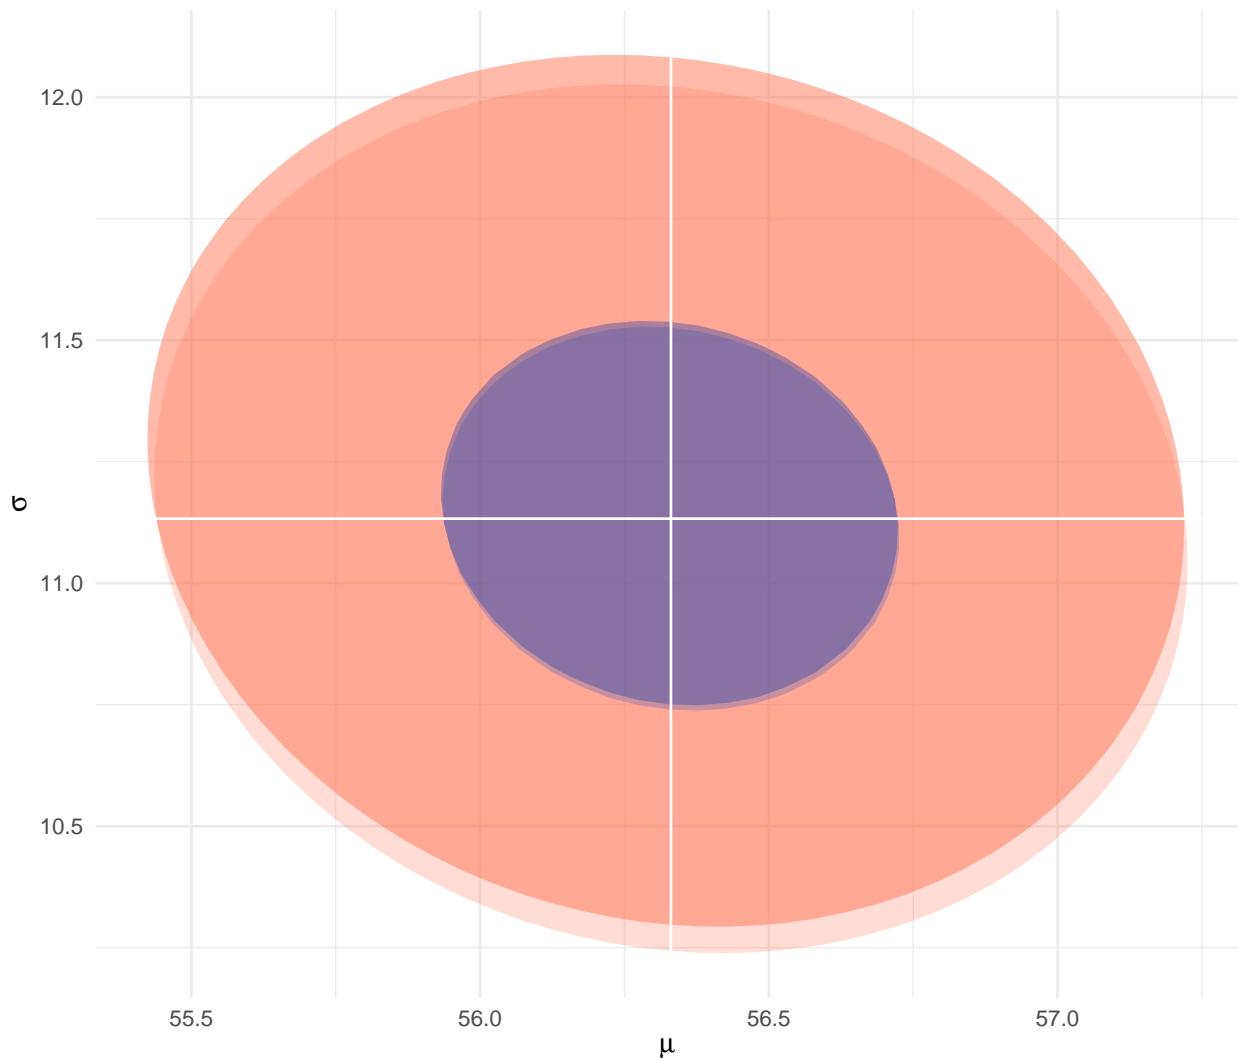

Figure 3: 99 and 95% confidence regions based on cut in the deviances. The stronger one is the likelihood-based, the other is the quadratic approximation (a.k.a., Wald based-interval).

Exercice 2: dist. Gaussiana bivariada

Seja $(x_i, y_i), \dots, (x_n, y_n)$ uma amostra aleatória de uma distribuição normal bivariada com média zero e matriz de covariância:

$$\Sigma = \sigma^2 \begin{bmatrix} 1 & \rho \\ \rho & 1 \end{bmatrix}.$$

(a) Mostrar que a matriz de informação de Fisher é dada por

$$\begin{bmatrix} \frac{n}{\sigma^4} & -\frac{n\rho}{\sigma^2(1-\rho^2)} \\ -\frac{n\rho}{\sigma^2(1-\rho^2)} & \frac{n(1+\rho^2)}{1-\rho^2} \end{bmatrix}.$$

$$\begin{aligned}
 & \left[\underbrace{\sigma^2 \ln^2[L]}_{1-R^2} \right] \\
 & \boxed{-n \ln \sigma^2 - \frac{n}{2} \ln(1-R^2)} \\
 & \quad \boxed{-\frac{\sum x^2}{2(1-R^2)\sigma^2} + \frac{2R\sum xy}{2(1-R^2)\sigma^2} - \frac{\sum y^2}{2(1-R^2)\sigma^2}} \\
 & \hat{l}(\sigma^2) = -\frac{n}{\sigma^2} + \frac{\sum x^2 - 2R\sum xy + \sum y^2}{2(1-R^2)\sigma^4} \\
 & l''(\sigma^2) = \frac{n}{\sigma^4} - \frac{(\sum x^2 - 2R\sum xy + \sum y^2)}{2(1-R^2)\sigma^6} \\
 & = \frac{n}{\sigma^4} - \frac{\sum x^2 - 2R\sum xy + \sum y^2}{(1-R^2)\sigma^6} \\
 & \mathbb{E}[-H] = \frac{1}{(1-R^2)\sigma^6} \mathbb{E}[\sum x^2 - 2R\sum xy + \sum y^2] - \frac{n}{\sigma^4} \\
 & = \frac{1}{(1-R^2)\sigma^6} \left[n(\mathbb{E}[x]^2 + \mathbb{E}^2[x]) - 2Rn\mathbb{E}[xy] + n(\mathbb{E}[y]^2 + \mathbb{E}^2[y]) \right] - \frac{n}{\sigma^4}
 \end{aligned}$$

Figure 4: Verossimilhança, já em log, apenas com os componentes relevantes. Derivadas em relação a σ^2 e início do cálculo de seu componente na Informação de Fisher.

$$\begin{aligned}
 \mathbb{E}[-H] &= \frac{1}{(1-R^2)\sigma^2} [n\sigma^2 - 2Rn\mathbb{E}[xy] + n\sigma^2] - \frac{n}{\sigma^4} \\
 &= \frac{2n(\sigma^2 - R\mathbb{E}[xy])}{(1-R^2)\sigma^6} - \frac{n}{\sigma^4} = \frac{2n(\sigma^2 - R(R\sigma^2))}{(1-R^2)\sigma^6} - \frac{n}{\sigma^4} \\
 &= \frac{2n\sigma^2(1-R^2)}{(1-R^2)\sigma^6} - \frac{n}{\sigma^4} = \frac{2n}{\sigma^4} - \frac{n}{\sigma^4} = \boxed{\frac{n}{\sigma^4}}
 \end{aligned}$$

Figure 5: Componente 11 da Informação de Fisher de ordem 2x2.

$$\begin{aligned}
\frac{\partial^2 I}{\partial \sigma^2 \partial R} &= \frac{\partial}{\partial R} \left[\frac{\sum X^2}{2(1-R^2)\sigma^4} - \frac{R\sum XY}{2(1-R^2)\sigma^4} + \frac{\sum Y^2}{2(1-R^2)\sigma^4} \right] \\
&= -\frac{\sum X^2}{2\sigma^4} (1-R^2)^{-2} (-2R) - \frac{\sum XY (1-R^2)\sigma^4 - R\sum XY (-2R)\sigma^4}{[2(1-R^2)\sigma^4]^2} - \frac{\sum Y^2}{2\sigma^4} (1-R^2)^{-2} (-2R) \\
&= \frac{\cancel{R}\sum X^2}{\cancel{(1-R^2)^2}\sigma^4} - \frac{\sum XY \cancel{(1-R^2)\sigma^4}}{\cancel{(1-R^2)^2}\sigma^8} - \frac{2R^2\sigma^4 \sum XY}{\sigma^8 (1-R^2)^2} + \frac{\cancel{R}\sum Y^2}{\cancel{(1-R^2)^2}\sigma^4} \\
&= \frac{R\sum X^2}{(1-R^2)^2\sigma^4} - \frac{\sum XY}{(1-R^2)\sigma^4} - \frac{2R^2\sum XY}{(1-R^2)^2\sigma^4} + \frac{R\sum Y^2}{(1-R^2)^2\sigma^4} \\
&= \frac{R\sum X^2 - (1-R^2)\sum XY - 2R^2\sum XY + R\sum Y^2}{(1-R^2)^2\sigma^4} = \frac{R\sum X^2 - \sum XY - R^2\sum XY + R\sum Y^2}{(1-R^2)^2\sigma^4} \\

Exercice 3: regressão Gaussiana

Considere os dados da tabela a seguir (adaptados/modificados de Montgomery & Runger, 1994) aos quais deseja-se ajustar um modelo de regressão linear simples relacionando a variável resposta Y (pureza em %) a uma variável explicativa X (nível de hidrocarbonetos).

| | | | | | | | | | | |
|---|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| X | 0.99 | 1.02 | 1.15 | 1.29 | 1.46 | 1.36 | 0.87 | 1.23 | 1.55 | 1.40 |
| Y | 99.01 | 89.05 | 91.43 | 93.74 | 96.73 | 94.45 | 87.59 | 91.77 | 99.42 | 93.65 |
| X | 1.19 | 1.15 | 0.98 | 1.01 | 1.11 | 1.20 | 1.26 | 1.32 | 1.43 | 0.95 |
| Y | 93.54 | 92.52 | 90.56 | 89.54 | 89.85 | 90.39 | 93.25 | 93.41 | 94.98 | 87.33 |

<r code>

```
data_3 <- data.frame(
  x = c(.99, 1.02, 1.15, 1.29, 1.46, 1.36, .87, 1.23, 1.55, 1.4,
        1.19, 1.15, .98, 1.01, 1.11, 1.2, 1.26, 1.32, 1.43, .95),
  y = c(99.01, 89.05, 91.43, 93.74, 96.73, 94.45, 87.59, 91.77, 99.42,
        93.65, 93.54, 92.52, 90.56, 89.54, 89.85, 90.39, 93.25, 93.41,
        94.98, 87.33))
```

(a) Encontre a função de verossimilhança.

Assuming a Normal distribution for $Y|X$, we have the following log-likelihood, in matrixial form

$$\begin{aligned} l(\theta; Y) &= -\frac{n}{2} \log 2\pi - n \log \sigma - \frac{1}{2\sigma^2} \|Y - X\beta\|^2 \\ &= \text{constant} - n \log \sigma - \frac{1}{2\sigma^2} \|Y - X\beta\|^2, \end{aligned}$$

were $\theta = [\beta_0 \ \beta_1 \ \sigma]^\top$, $\beta = [\beta_0 \ \beta_1]^\top$, and $\mu_i = \beta_0 + \beta_1 x_i$.

<r code>

```
gaussian3_reg <- function(b0, b1, sigma) {
  mu <- b0 + b1 * data_3$x
  lk1 <- sum(dnorm(data_3$y, mean = mu, sd = sigma, log = TRUE))
  return(-lk1)
}
```

(b) Encontre as estimativas de máxima verossimilhança.

```
<r code>
model_fit <- mle2(gaussian3_reg,
                     start = list(b0 = min(data_3$y), b1 = 1.5,
                                   sigma = sd(data_3$y)))
(par_est <- model_fit@coef)

b0          b1          sigma
77.988429  12.225489  2.343799
```

Just checking...

```
<r code>

lm(y ~ x, data_3)$coef # beta_0 and beta_1

(Intercept)           x
77.98996    12.22453

par_est[[3]]**2 # sigma^2

[1] 5.493392

(summary(lm(y ~ x, data_3))$sigma**2) * (nrow(data_3) - 2) / nrow(data_3)

[1] 5.493386
```

Checked, ✓.

(c) Obtenha a verossimilhança conjunta para os parâmetros β_0 e β_1 :

Considerando σ fixo com valor igual à sua estimativa,

```
<r code>
gaussian3_deviance <- function(b0_grid, b1_grid, theta_est) {
  b0_est <- theta_est[[1]]
  b1_est <- theta_est[[2]]
  sigma_est <- theta_est[[3]]
  lkl_grid <- gaussian3_reg(b0_grid, b1_grid, sigma_est)
  lkl_est <- gaussian3_reg(b0_est, b1_est, sigma_est)
```

```

    return(2 * (lkl_grid - lkl_est))
}
gaussian3_deviance <- Vectorize(gaussian3_deviance,
                                   c("b0_grid", "b1_grid"))

```

(b) Encontre as estimativas de máxima verossimilhança.

```

<r code>
model_fit <- mle2(gaussian4_reg,
                     start = list(b0 = min(data_4$y), b1 = 1.5,
                                  sigma = sd(data_4$y)))
(par_est <- model_fit@coef)

b0          b1          sigma
78.410145 11.869453 2.432607

```

Considering only the exact observations, we get these β 's

```

<r code>
lm(y ~ x, data_4)

```

Call:

```
lm(formula = y ~ x, data = data_4)
```

Coefficients:

| (Intercept) | x |
|-------------|-------|
| 80.58 | 10.04 |

(c) Obtenha a verossimilhança conjunta para os parâmetros β_0 e β_1 :

Considerando σ fixo com valor igual à sua estimativa,

```

<r code>
gaussian4_deviance <- function(b0_grid, b1_grid, theta_est) {
  b0_est <- theta_est[[1]]
  b1_est <- theta_est[[2]]
  sigma_est <- theta_est[[3]]
  lkl_grid <- gaussian4_reg(b0_grid, b1_grid, sigma_est)
  lkl_est <- gaussian4_reg(b0_est, b1_est, sigma_est)
  return(2 * (lkl_grid - lkl_est))
}
gaussian4_deviance <- Vectorize(gaussian4_deviance,
                                    c("b0_grid", "b1_grid"))
b0_grid <- seq(67, 90, length.out = 50)
b1_grid <- seq(2, 22, length.out = 50)

```

```

deviance_grid <- outer(b0_grid, b1_grid, FUN = gaussian4_deviance,
                        theta_est = par_est)
rownames(deviance_grid) <- b0_grid
colnames(deviance_grid) <- b1_grid
deviance_grid <- reshape2::melt(deviance_grid)
bigaussian_trans(deviance_grid,
                 xlab = expression(beta[0]), ylab = expression(beta[1]),
                 tag = NULL, par_est = par_est) +
  labs(title = "Deviance contour", subtitle = "MLE's, in white.")

```

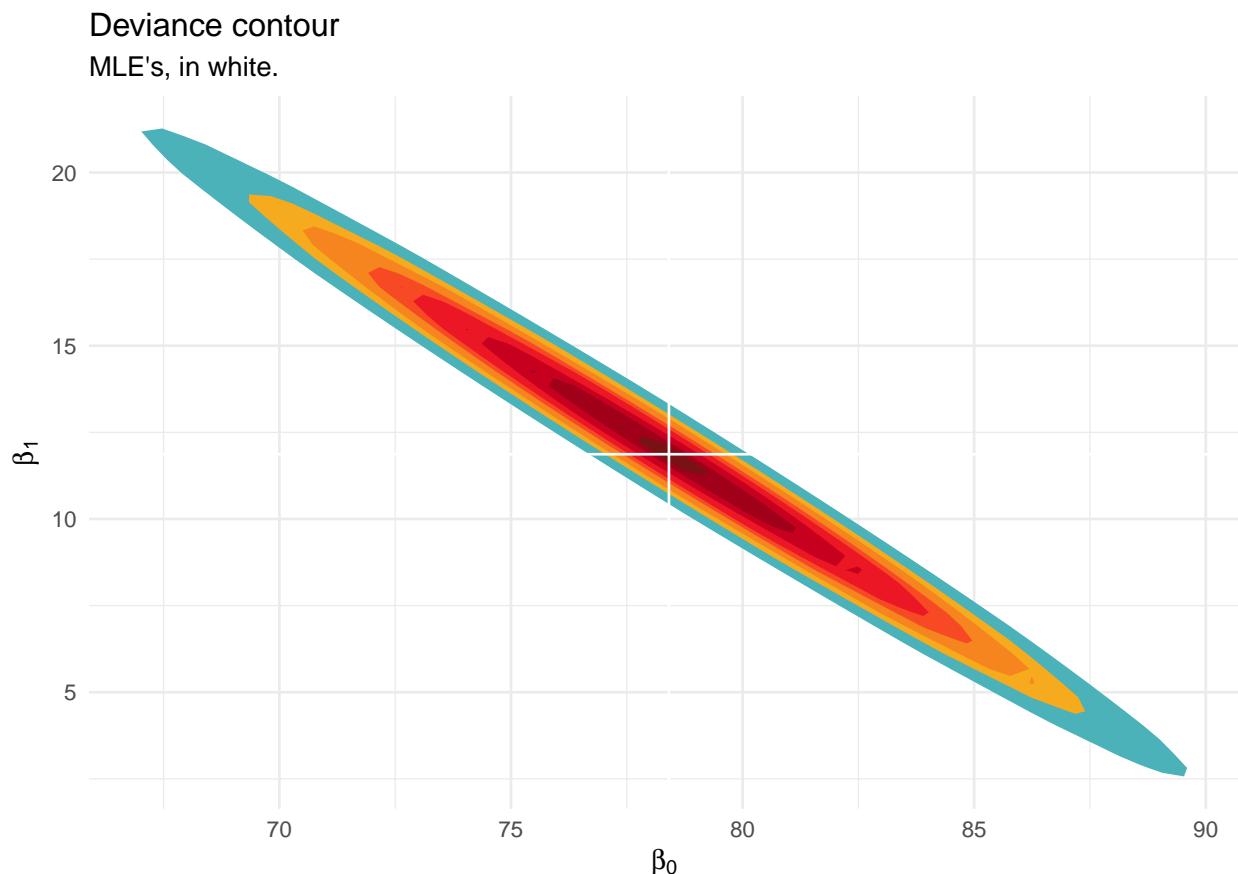

Figure 17: Deviance contour for the β 's of a Gaussian linear regression with some censored observations and with the standard deviation fixed in its MLE.

Obtendo a verossimilhança perfilhada em relação a σ .

<r code>

```
sigma_grid <- seq(1, 17.5, length.out = 50)
beta_perf <- matrix(0, nrow = length(sigma_grid), ncol = 3)
for (i in seq(sigma_grid)) {
  beta_perf[i, ] <- unlist(
    mle2(gaussian4_reg, start = list(b0 = min(data_4$y), b1 = 1.5),
          data = list(sigma = sigma_grid[i]))@details[1:2])
}
ggplot() + theme_minimal() +
  geom_line(aes(x = sigma_grid, y = -beta_perf[, 3]), size = 1.5) +
  geom_vline(xintercept = par_est[3], linetype = "dashed") +
  labs(x = expression(sigma), y = NULL,
       title = expression(sigma ~ "profile likelihood"),
       subtitle = "MLE, in dashed.")
```

σ profile likelihood

MLE, in dashed.

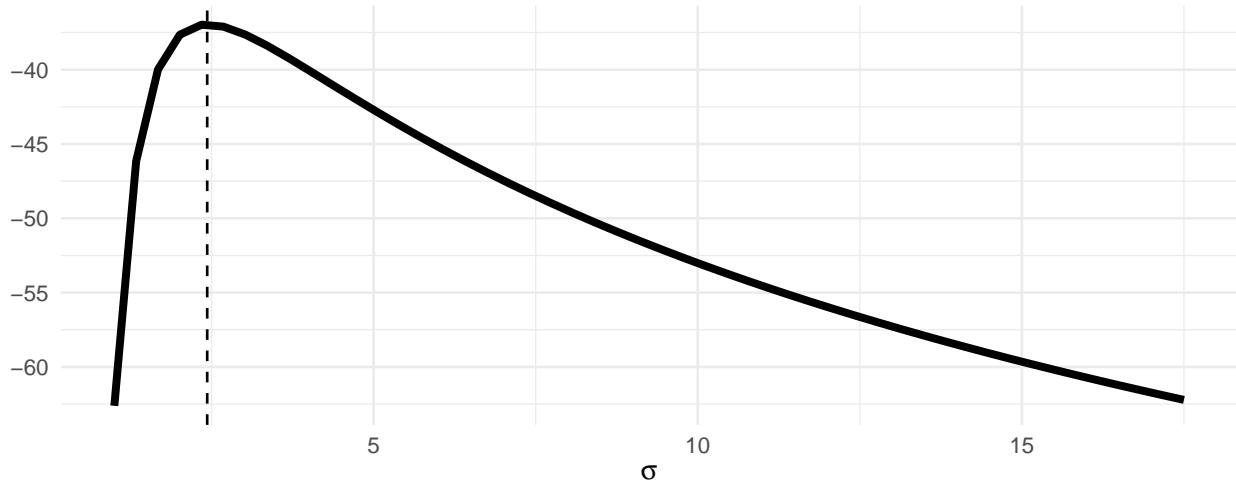

Figure 18: σ profile likelihood in a Gaussian linear regression with some censored observations. In dashed, the MLE.

And how the β 's fluctuates across the grid of σ ?

<r code>

```
summary(beta_perf[, 1]) # beta_0
Min. 1st Qu. Median Mean 3rd Qu. Max.
70.40 72.35 74.70 74.68 76.84 79.54
```

```

summary(beta_perf[, 2]) # beta_1

Min. 1st Qu. Median Mean 3rd Qu. Max.
10.90 13.27 15.21 15.23 17.31 19.09

```

Very few, as expected. Since the estimation of β doesn't depend on σ .

(d) Obtenha a verossimilhança perfilhada para os parâmetros β_0 e β_1 individualmente.

```

<r code>
coef_profile <- function(grid, coef = c("b0", "b1")) {
  n <- length(grid)
  prof <- numeric(n)
  for (i in seq(n)) {
    prof[i] <-
      switch(coef,
        "b0" = mle2(gaussian4_reg,
